## Problem 1

S. S. Pillai proved in [1] the following theorem. When  $m \leq 16$ , in every set of  $m$  consecutive integers, there is at least one integer which is relatively prime to all the others in the set. He realized that the smallest number  $m$  for which there is a sequence of  $m$  consecutive integers without a number relatively prime to all others is  $m = 17$ . Find the smallest natural number  $n$  such that in the sequence  $n, n + 1, \dots, n + 16$  there is no number relatively prime to the others.

[1] S.S. Pillai, *On  $m$  consecutive integers-I.*, Proceedings of the Indian Academy of Sciences Vol 11/1, pp 6-12 (1940).

## SOLUTION

The answer is  $n = 2184$ . We can find it using a program, like this Maxima worksheet. (It is in wxMaxima environment.)

```

wxMaxima 19.11.0 [problem.wmx ]
File Edit View Cell Maxima Equations Algebra Calculus Simplify List Plot Numeric Help
(%i1) block(m:17,
      n:0,
      while m#a do block(a:0,
        n:n+1,
        for b:0 thru m-1 do
          for c:n thru n+m-1 do
            if (n+b#c and gcd(n+b,c)#1) then block(c:n+m-1,
              a:a+1)),
      print(n));
2184
(%o1) 2184
Maxima is ready for input. Ready for user input

```

## Problem 2

Draw all the diagonals of a regular polygon. How many interior intersections are there on a given diagonal? For example, the figure shows a regular 18-gon and all its diagonals. The diagonal connecting the opposite vertices has 27 interior intersection points.

Figure. The regular 18-gon with its diagonals. There are 27 interior intersection points on the longest diagonal: 8 two-line intersections, 12 three-line intersections, 6 five-line intersections, and 1 nine-line intersection

## Solution

Give the vertices of the regular  $n$ -gon with a serial number counterclockwise after the vertex 0 is fixed (Figure 1). A diagonal can thus be defined by two numbers. Fix the diagonal  $(0, i)$  and intersect it with the diagonal  $(j, k)$  as shown in the figure. Write the law of sines in the triangles  $BMC$  and  $AMB$ :

$$\frac{x}{z} = \frac{\sin(n-k)\alpha}{\sin(i-j)\alpha} = \frac{\sin k\alpha}{\sin(i-j)\alpha}, \quad \frac{z}{y} = \frac{\sin(k-i)\alpha}{\sin j\alpha},$$

where  $\alpha = \frac{\pi}{n}$ . From this we can conclude that

$$\frac{x}{y} = \frac{\sin k\alpha}{\sin(i-j)\alpha} \cdot \frac{\sin(k-i)\alpha}{\sin j\alpha}.$$

If we fix  $i$ , then  $j=1, 2, \dots, i-1$ , and  $k=i+1, i+2, \dots, n-1$ . It means that the maximum number of interior intersection points is  $(i-1) \cdot (n-i-1)$ . However, we may have multiple intersection points. Then, we need to test whether different diagonals  $(j, k)$  and  $(j', k')$  produce the same ratio or not. If not, we have a double intersection point (i.e.  $(j, k)$  intersects  $(0, i)$ ). If two diagonals produce the same ratio, then the intersection is triple (i.e.  $(j, k)$  and  $(j', k')$  intersects  $(0, i)$  at the same point), and so on.

Figure 1.
